

## Features

- PCIe Gen5 Phase Jitter < 80fs rms
- 3.3V operation voltage
- 85Ω differential Low-Power HCSL (LP-HCSL) outputs eliminate 32 resistors
- selectable SMBus addresses
- Supports 0%, -0.3% and -0.5% spread-spectrum amounts
- 6 mm x 6 mm TQFN-48L

## Output Features

- 1 – 25MHz output pairs
- 6 – 100MHz output pairs
- 2 – MXCLK output pairs multiplexable between 100MHz and 25MHz
- Dedicated Platform Time Input clock

## Application

- Cloud/High-performance Computing
- nVME Storage
- Networking
- PCIe switch

## Description

The RS2CG2008 is a single-chip, PCIe Gen5 clock synthesizer. It is designed to work as a complete clock solution which matches PCIe Gen5 specification or in combination with DB2000QL-compliant clock buffers. It is part of the next generation clock generator family supporting the latest dual and multi-socket Intel server platforms.

## PCIe Clocking Architecture

- Common Clocked (CC)
- Independent Reference (IR) with and without spread spectrum

## Platform Time Input

The RS2CG2008 support a dedicated Platform Time Input clock. These pins receive clock from another clock device to keep synchronization across servers. PFT\_IN allows different devices to frequency lock the 25 MHz clocks to a single time base. The local 25 MHz frequency locks to the PFT\_IN clock if it is present. If PFT\_IN is not present, the local 25MHz frequency is sourced from the local crystal.

**Figure 2. PFT Bias Network**

## Output Enable Control

The outputs of RS2CG2008 is controlled by using the SMBus output enable bits. Any of the 9 outputs have dedicated SMBus output enable bits in Bytes[0:2] of the SMBus register set that can enable or disable the clock outputs. The Output Enable bits in the SMBus registers are active high and are set to enable by default.

## Absolute Maximum Ratings

The absolute maximum ratings are stress ratings only. Stresses greater than those listed below can cause permanent damage to the device. Functional operation of the RS2CG2008 at absolute maximum ratings is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

**Table 5. Absolute Maximum Ratings**

Parameter	Symbol	Conditions	MIN	TYP	MAX	Units	Notes
Supply Voltage	V <sub>DDX</sub>				3.9	V	1
3.3V Input High Voltage	V <sub>IH</sub>				3.9	V	2
3.3V Input Low Voltage	V <sub>IL</sub>		-0.5			V

Clock/Data Rise Time	t <sub>R</sub>	—	1000	—	1000	—	300	—	300	ns	6
Time in which a device must be operational after power-on reset	t <sub>POR</sub>		5		500		5		500	ms	7

<sup>1</sup> After this period, the first clock is generated.

<sup>2</sup> The RS2CG2008 device maintains 300ns data hold time for backwards compatibility with the SMBus 2.0 specification. Newer versions of the SMBus specification call out 0ns data hold time for both 100kHz and 400kHz classes.

<sup>3</sup> The RS2CG2008 provided additional SMBus protection by implementing a timeout for SDA being held low in excess of t<sub>TIMEOUT</sub>, in addition to the SCLK low timeout.

<sup>4</sup> Devices participating in a transfer can abort the transfer in progress and release the bus when any single clock low interval exceeds the value of t<sub>TIMEOUT</sub>, Minimum. After the master in a transaction detects this condition, it must generate a stop condition within or after the current data byte in the transfer process. Devices that have detected this condition must reset their communication and be able to receive a new START condition no later than t<sub>TIMEOUT</sub>, Maximum. Typical device examples include the host controller, and embedded controller, and most devices that can master the SMBus. Some simple devices do not contain a clock low drive circuit; this simple kind of device typically may reset its communications port after a start or a stop condition. A timeout condition can only be ensured if the device that is forcing the timeout holds the SMBCLK low for t<sub>TIMEOUT</sub>, Maximum or longer.

<sup>5</sup> t<sub>HIGH</sub>, Maximum provides a simple guaranteed method for masters to detect bus idle conditions. A master can assume that the bus is free if it detects that the clock and data signals have been high for greater than t<sub>HIGH</sub>, Maximum.

<sup>6</sup> The rise and fall time measurement limits are defined as follows:

Rise Time Limits: (V<sub>IL</sub>, MAX - 0.15V) to (V<sub>IH</sub>, MIN + 0.15V)

Fall Time Limits: (V<sub>IH</sub>, MIN + 0.15 V) to (V<sub>IL</sub>, MAX - 0.15V)

<sup>7</sup> Power must be applied and PWRGD must be a 1 for the SMBus to be active.

<sup>1</sup> The Refclk jitter is measured after applying the filter functions found in PCI Express Base Specification 5.0, Revision 1.0. See the [Test Loads](#) section of the data sheet for the exact measurement setup. Values for the Common Clock architecture are calculated with spread off and spread on at -0.5%. SRIS values are calculated for spread off and spread on at ≤ -0.3%. The worst case results for each data rate are summarized in this table. If oscilloscope data is used, equipment noise is removed from all results. See Test Load for PCIe Phase Jitter Measurements.

- <sup>2</sup> Jitter measurements shall be made with a capture of at least 100,000 clock cycles captured by a real-time oscilloscope (RTO) with a sample rate of 20 GS/s or greater. Broadband oscilloscope noise must be minimized in the measurement. The measured PP jitter is used (no extrapolation) for RTO measurements. Alternately - Jitter measurements may be made with a Phase Noise Analyzer (PNA) extending (flat) and integrating and folding the frequency content up to an offset from the carrier frequency of at least 200MHz (at 300MHz absolute frequency) below the Nyquist frequency. For PNA measurements for the 2.5GT/s data rate, the RMS jitter is converted to peak to peak jitter using a multiplication factor of 8.83. In the case where real-time oscilloscope and PNA measurements have both been done and produce different results, the RTO result must be used.
- <sup>3</sup> SSC spurs from the fundamental and harmonics are removed up to a cutoff frequency of 2 MHz taking care to minimize removal of any non-SSC content.
- <sup>4</sup> Note that 0.7ps RMS is to be used in channel simulations to account for additional noise in a real system.
- <sup>5</sup> Note that 0.25ps RMS is to be used in channel simulations to account for additional noise in a real system.
- <sup>6</sup> The PCI Express Base Specification 5.0, Revision 1.0 provides the filters necessary to calculate SRIS jitter values, however, it does not provide specification limits, hence the n/a in the Limit column. SRIS values are informative only. In general, a clock operating in an SRIS system must be twice as good as a clock operating in a Common Clock system. For RMS values, twice as good is equivalent to dividing the CC value by  $\sqrt{2}$ . And additional consideration is the value for which to divide by  $\sqrt{2}$ . The conservative approach is to divide the ref clock jitter limit, and the case can be made for dividing the channel simulation values by  $\sqrt{2}$ , if the ref clock is close to the Tx clock input. An example for Gen4 is as follows. A "rule-of-thumb" SRIS limit would be either  $0.5\text{ps RMS}/\sqrt{2} = 0.35\text{ps RMS}$  if the clock chip is far from the clock input, or  $0.7\text{ps RMS}/\sqrt{2} = 0.5\text{ps RMS}$  if the clock chip is near the clock input.

- <sup>1</sup> Guaranteed by design and characterization, not 100% tested in production.
- <sup>2</sup> Measured from differential waveform.
- <sup>3</sup> Slew rate is measured through the Vswing voltage range centered around differential 0 V. This results in a  $\pm 150\text{mV}$  window around differential 0V.
- <sup>4</sup> Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a  $\pm 75\text{mV}$  window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations.
- <sup>5</sup> Vcross is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).
- <sup>6</sup> The total variation of all Vcross measurements in any particular system. Note that this is a subset of Vcross\_min/max (Vcross absolute) allowed. The intent is to limit Vcross induced modulation by setting  $\Delta\text{-Vcross}$  to be smaller than Vcross absolute.
- <sup>7</sup> At default SMBus settings.
- <sup>8</sup> Includes 300mV of overshoot for Vmax and 300mV of undershoot for Vmin.

<sup>1</sup> PWRGD = 1, all outputs enabled.

<sup>2</sup> PWRGD = 0.

**Table 16. Power Supply Noise Profile**

TA = TAMB. Supply voltages per normal operation conditions; see [Test Loads](#) for loading conditions.

Parameter	Symbol	Conditions	MIN	TYP	MAX	Units	Notes
Power Supply Noise	V <sub>DD_AC</sub>	Single tone AC noise, swept.		40		mV	1
	V <sub>DDA_AC</sub>	VDD electrical noise > 20MHz.		20		mV	1
	V <sub>DDXO</sub>	VDD electrical noise 12kHz to 25MHz.		TBD		mV	1

<sup>1</sup> Peak-to-peak values. The device meets all AC/DC parameters in the presence of at least this much noise.

## Test Loads

**Table 17. Parameters for AC/DC Test Load**

$R_s (\Omega)$	$Z_o (\Omega)$	$L$ (cm)	$C_L$ (pF)
Internal	85	25.4	2

**Figure 11. Test Load for PCIe Phase Jitter Measurements**

**Table 18. Parameters for PCIe Gen5 Jitter Measurement**

$R_s (\Omega)$	$Z_o (\Omega)$	$L$ (cm) *	$C_L$ (pF)
Internal	85	25.4	N/A

\* Note: PCIe Gen5 specifies  $L = 0$ cm.  $L = 25.4$ cm is more conservative.

## SMBus Interface Information

### Write Operation

- Controller (host) sends a start bit
- Controller (host) sends the write address
- RSM clock will acknowledge
- Controller (host) sends the beginning byte location = N
- RSM clock will acknowledge
- Controller (host) sends the byte count = X
- RSM clock will acknowledge
- Controller (host) starts sending Byte N through Byte N+X-1
- RSM clock will acknowledge each byte one at a time
- Controller (host) sends a stop bit

### Read Operation

- Controller (host) will send a start bit
- Controller (host) sends the write address
- RSM clock will acknowledge
- Controller (host) sends the beginning byte location = N
- RSM clock will acknowledge
- Controller (host) will send a separate start bit
- Controller (host) sends the read address
- RSM clock will acknowledge
- RSM clock will send the data byte count = X
- RSM clock sends Byte N+X-1
- RSM clock sends Byte 0 through Byte X (if X(H) was written to Byte 8)
- Controller (host) will need to acknowledge each byte
- Controller (host) will send a not acknowledge bit
- Controller (host) will send a stop bit

**Note:**

The MXCK\_SEL Control (bit 6) should be set to '1' then MXCK [2:1] outputs are controlled with MXCK\_SEL bit (bit 7).

**Table 23. Byte 3: PFT Control Register**

Bit	Description	Bit = 0	Bit = 1	Type	Default	Output(s) Affected
7	Realtime Readback of PFT_LOST#	PFT_LOST# low	PFT_LOST# high	R	Realtime	
6	Stop Delta Frequency Update (Byte 4 and 5)	Disabled	Enabled	R/W	0	Reserved
5	Clear Delta Frequency Registers (Byte 4 and 5)		All bits reset to 0	RW	0	Reserved
4	Reserved				0	Reserved
3	Reserved				0	Reserved
2	Reserved				0	Reserved
1	Reserved				0	Reserved
0	Reserved				0	Reserved

**Note:**

Prior to reading the delta frequency between PFT\_IN and local 25MHz XO (Bytes 4 and 5), user should set bit 6 to prevent the case where one of the PFT Frequency Delta Registers is read before and the other after the internal update. The bit should be cleared after the read has been completed.

**Table 24. Byte 4: PFT Frequency Delta Register 0 (Least Significant Byte)**

Bit	Description	Bit = 0	Bit = 1	Type	Default	Output(s) Affected
7	PFT – 25 MHz XO bit 7			R	Realtime	
6	PFT – 25 MHz XO bit 6			R	Realtime	
5	PFT – 25 MHz XO bit 5			R	Realtime	
4	PFT – 25MHz XO bit 4			R	Realtime	
3	PFT – 25 MHz XO bit 3			R	Realtime	
2	PFT – 25 MHz XO bit 2			R	Realtime	
1	PFT – 25 MHz XO bit 1			R	Realtime	
0	PFT – 25 MHz XO bit 0			R	Realtime	

**Note:**

These bits contain the least significant byte of average PPM difference between the PFT clock and the local 25MHz reference.

**Table 25. Byte 5: PFT Frequency Delta Register 1 (Most Significant Byte)**

Bit	Description	Bit = 0	Bit = 1	Type	Default	Output(s) Affected
7	PFT – Sign Bit	Positive Number	Negative Number	R	Realtime	
6	PFT – 25 MHz XO bit 14			R	Realtime	
5	PFT – 25 MHz XO bit 13			R	Realtime	
4	PFT – 25 MHz XO bit 12			R	Realtime	
3	PFT – 25 MHz XO bit 11			R	Realtime	
2	PFT – 25 MHz XO bit 10			R	Realtime	
1	PFT – 25 MHz XO bit 9			R	Realtime	
0	PFT – 25 MHz XO bit 8			R	Realtime	

**Note:**

These bits contain the most significant byte of average PPM difference between the PFT clock and the local 25MHz reference. The representation is 2's complement, signed magnitude with Byte 5 bit 7 being the sign bit.
